 Supporting Information

**ABSTRACT:** Proteasomes are broadly expressed key components of the ubiquitin-dependent protein degradation pathway containing catalytically active subunits ( $\beta 1$ ,  $\beta 2$ , and  $\beta 5$ ). LMP7 ( $\beta 5i$ ) is a subunit of the immunoproteasome, an inducible isoform that is predominantly expressed in hematopoietic cells. Clinically effective pan-proteasome inhibitors for the treatment of multiple myeloma (MM) nonselectively target LMP7 and other subunits of the constitutive proteasome and immunoproteasome with comparable potency, which can limit the therapeutic applicability of these drugs. Here, we describe the discovery and structure-based hit optimization of novel amido boronic acids, which selectively inhibit LMP7 while sparing all other subunits. The exploitation of structural differences between the proteasome subunits culminated in the identification of the highly potent, exquisitely selective, and orally available LMP7 inhibitor **50** (M3258). Based on the strong antitumor activity observed with M3258 in MM models and a favorable preclinical data package, a phase I clinical trial was initiated in relapsed/refractory MM patients.

## INTRODUCTION

Proteasomes are large multicatalytic complexes that are central components of the cellular machinery for maintenance of protein homeostasis.<sup>1–3</sup> The barrel-shaped 20S core particle of proteasomes consists of 28 subunits assembled in four rings of seven subunits each. The core particle of the broadly expressed constitutive proteasome (cP) contains the distinct proteolytic subunits  $\beta 1$  (*PSMB6*),  $\beta 2$  (*PSMB7*), and  $\beta 5$  (*PSMB5*), which possess caspase-like, trypsin-like, and chymotrypsin-like proteolytic activity, respectively. The differential substrate preferences of each subunit enable the processing of diverse ubiquitinated proteins in cells. A distinct core proteasome particle called the immunoproteasome (iP) contains the unique proteolytic subunits  $\beta 1i$  (*LMP2* and *PSMB9*),  $\beta 2i$  (*MECL1* and *PSMB10*), and  $\beta 5i$  (*LMP7* and *PSMB8*) with chymotrypsin-like, trypsin-like, and chymotrypsin-like activity, respectively. The iP is predominantly expressed in cells of hematolymphoid origin<sup>4–7</sup> and can be induced in other cell types by exposure to inflammatory stimuli such as IFN $\gamma$  or TNF $\alpha$ .<sup>8</sup>

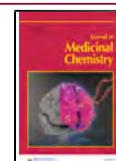

Aside from its essential function in the maintenance of protein homeostasis, the iP also degrades pathogenic proteins and generates peptidic fragments, which are more efficiently loaded on the class I major histocompatibility complex (MHC I) for antigen presentation compared to cP-derived peptides.<sup>2</sup> Furthermore, the iP-specific proteolytic subunits, in particular

LMP7, play an essential role in restoring homeostasis in cells under elevated proteotoxic or oxidative stress.<sup>9</sup>

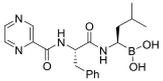

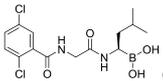

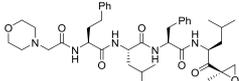

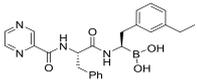

The essentiality of proteasomes for the viability of multiple myeloma (MM) cells has been underpinned by the approval and wide application of the proteasome inhibitors bortezomib, carfilzomib, and ixazomib. These drugs interfere with the activity of multiple cP and iP proteolytic subunits.<sup>10</sup> While this nonselective mechanism delivers robust clinical efficacy in MM, it is also associated with diverse toxicities including thrombocytopenia, neutropenia, and cardiotoxicity,<sup>10</sup> which can lead to dose reductions, less frequent regimens, or cessation of treatment and thus limit the therapeutic potential of these drugs.<sup>11–14</sup> The restricted expression and unique functional features of iP-specific subunits have led to considerable interest in the potential of selective iP inhibitors in diverse disease settings.<sup>3,12,15</sup> Recent reports have suggested that therapeutic efficacy in preclinical models of inflammation and autoimmunity requires dual inhibition of the iP subunits LMP2 and LMP7.<sup>15–18</sup> However, in the case of preclinical

cancer models, the therapeutic effects of inhibition of individual iP proteolytic subunits or multiple subunits remain less well characterized, with most preclinical reports to date only describing the activity of dual LMP2/7 inhibitors or compounds with only partial selectivity against the cP subunit  $\beta$ 5.<sup>19–25</sup>

The work published in this paper is based on the hypothesis that selective LMP7 inhibition could potentially achieve antitumor activity in B cell-derived malignancies.<sup>3,12,13</sup> Although in recent years substantial progress has been made in the design of selective LMP7 inhibitors, to our knowledge, no compound has been published to date, which has properties enabling oral administration, in order to evaluate this hypothesis. We have generated highly potent LMP7 inhibitors that demonstrate exquisite selectivity against all other proteolytic subunits of the iP and cP. Compound **50** (M3258) also demonstrated an attractive overall profile with regard to physicochemical and drug metabolism and pharmacokinetic (DMPK) properties and delivered robust *in vivo* efficacy and target inhibition in an MM xenograft model. These data supported the recent initiation of a phase I clinical trial of M3258 in relapsed/refractory MM patients (NCT04075721).

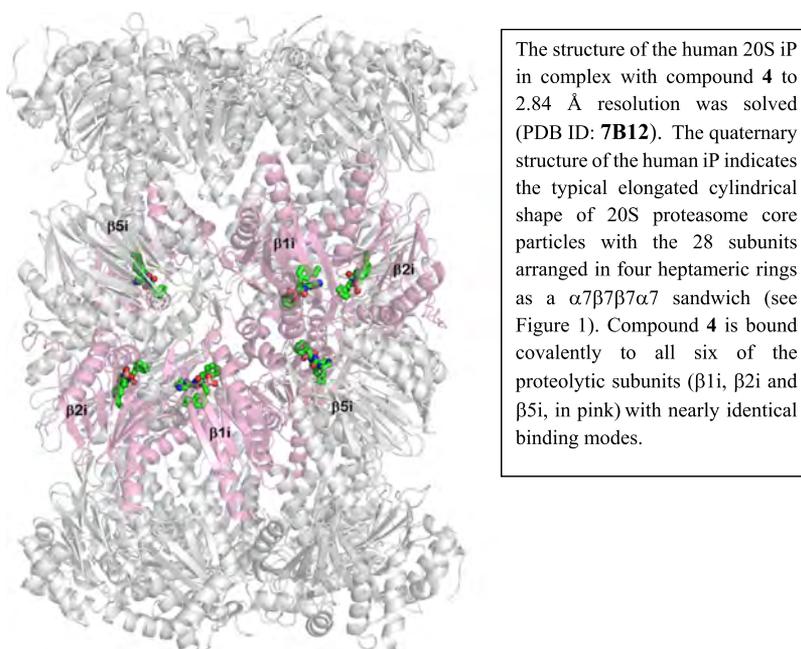

## RESULTS AND DISCUSSION

As a starting point, we evaluated the subunit inhibition profiles of the clinically approved proteasome inhibitors bortezomib, ixazomib, and carfilzomib (Table 1). The inhibition of each proteolytic subunit of iP ( $\beta$ 1i,  $\beta$ 2i, and LMP7) and cP ( $\beta$ 1,  $\beta$ 2, and  $\beta$ 5) was determined using fluorescence intensity assays applying specific substrates that undergo cleavage by the individual proteasome subunits. According to our data and in line with previous reports,<sup>26,27</sup> bortezomib and ixazomib displayed comparable subunit specificity with the highest activity against  $\beta$ 1i, LMP7, and  $\beta$ 5. In contrast, carfilzomib

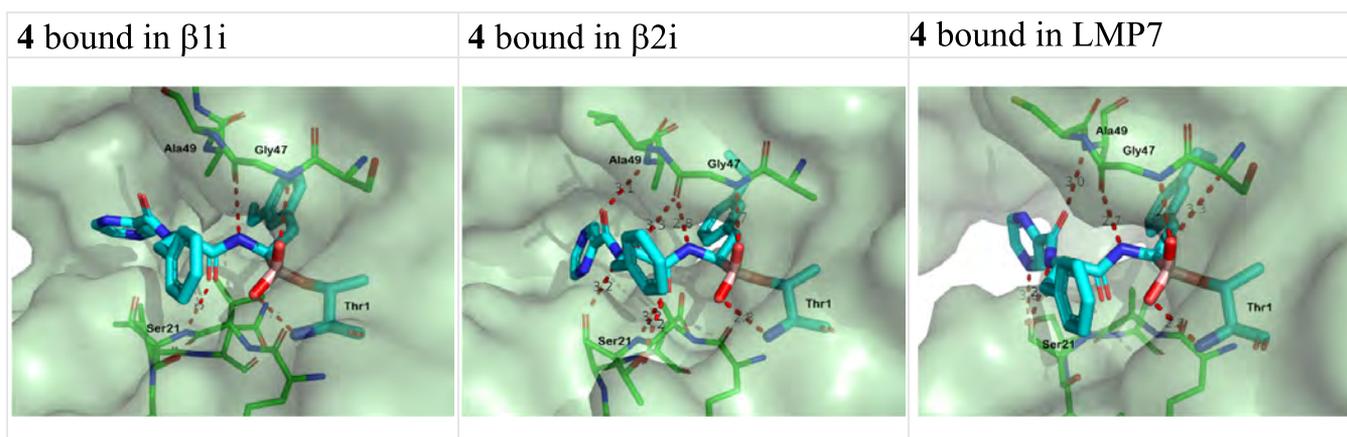

turned out to be less selective, inhibiting not only  $\beta$ 1i, LMP7, and  $\beta$ 5 but also  $\beta$ 2i and  $\beta$ 2 proteolytic activity. Each of these inhibitors contains an isobutyl group, which occupies the S1 pocket adjacent to the catalytically active site as a common motif.

Although the iP and cP possess overlapping substrate specificities, it is well established that the iP has a stronger preference for hydrophobic amino acids like tryptophan binding to S1 and is more effective in cleaving such substrates.<sup>28</sup> In contrast, the cP displays a greater preference for cleavage following smaller and polar amino acid residues. Crystallographic investigations from Huber et al. suggested that LMP7 has a larger S1 pocket than  $\beta$ 5 due to a Met45 conformation that allows access of sterically demanding groups to the binding pocket.<sup>29</sup> We speculated that these differences could possibly be exploited to generate more selective iP inhibitors. Furthermore, rationally designed LMP7-specific substrates, like (Ac-ANW)2R110 or Ac-ANW-AMC<sup>30</sup> containing a tryptophan to fill the S1 pocket, underline the ability of the S1 pocket to accommodate large bicyclic moieties. Very recently, the reported structures of the cP and chimeric immuno-constitutive proteasome variants in yeast and the electron microscopy report of the human iP<sup>31</sup> have been complemented by the crystal structure of an  $\alpha$ -aminoboronic acid derivative in complex with the *bona fide* human iP,<sup>17</sup> in which a large 2,4-dimethylphenyl moiety fills the S1 pocket.

**Cocrystal Structure of Compound 4 with the iP.** Since this information was unknown at the time at which we initiated our drug discovery program some years ago, our initial efforts focused on generating insights into the human iP structure. We were able to generate a cocrystal structure of the human iP with compound **4** (Table 1), which is a bortezomib derivative synthesized similar to reported methods.<sup>32</sup> Instead of an isobutyl group, **4** contains a more sterically demanding 3-ethyl-substituted benzyl moiety (Figure 1). Although **4** displayed

**Figure 1.** Human iP (S20 core particle) X-ray structure in complex with compound **4**.

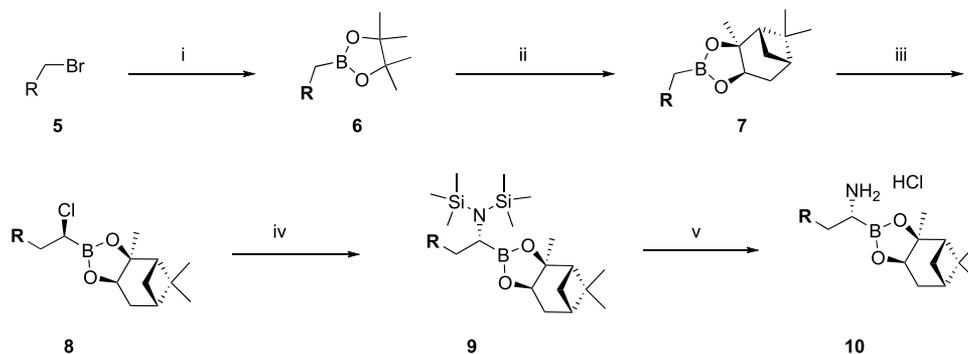

**Figure 2.** Binding modes of **4** in  $\beta 1i$ ,  $\beta 2i$ , and LMP7. The orientation of the ethyl-phenyl moiety in  $\beta 1i$  is flipped by roughly 180° compared to that in  $\beta 2i$  and LMP7. The hydrogen bonding network of compound **4** with the catalytic subunits is mostly built in an antiparallel  $\beta$ -sheet manner, interacting with the protein main chain in the substrate binding channel. The pyrazine group of **4** binds into the S3 pockets of the catalytic subunits, adopting several ring orientations, depending on the subunit type and on the neighboring protein chains.

### Scheme 1. Strategy to Increase LMP7 Specificity

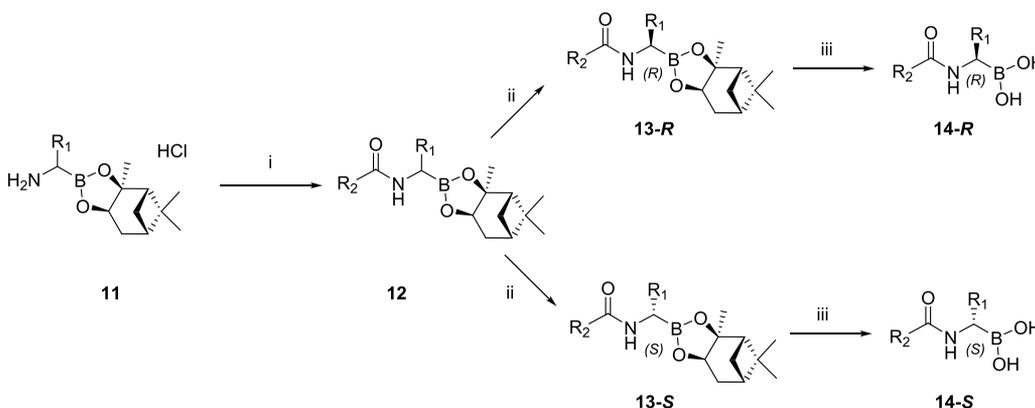

different potencies against  $\beta 1i$ ,  $\beta 2i$ , and LMP7, in the crystal structure, all subunits were found to be occupied, likely as a result of the high concentration used during cocrystallization (Figure 2). In each case, the boron atom covalently interacted with the nucleophilic oxygen lone pair of Thr1 and led to the formation of a tetrahedrally coordinated boronate adduct as expected. In the LMP7 subunit, the large 3-ethylphenyl group, replacing the isobutyl group of bortezomib, nicely filled the S1 pocket.

Compound **4** showed  $\sim 24$ -fold biochemical selectivity for LMP7 over  $\beta 5$ , contrasting to the  $\sim 2$ -fold selectivity measured with bortezomib (Table 1). Compound **4** contains an identical dipeptide residue, which adopts the known antiparallel  $\beta$ -sheet conformation.<sup>33</sup> The amide bond next to the active site is essential for activity and interacts with Ser21 and Gly47 in LMP7 through two strong hydrogen bonds, while the second amide group forms two hydrogen bonds with the peptidic backbone of the LMP7 subunit (Ala49 and Ser21). Similar

interactions were identified in  $\beta 2i$  (Thr21 replaces Ser21),  $\beta 1i$ , and in the  $\beta 5$  subunit of the cP. Despite the significant changes in S1 pocket selectivity, the H-bond network formed by the dipeptide residue of 4 did not result in a pronounced potency difference between subunits.

We therefore hypothesized that LMP7 selectivity could be gained by weakening this hydrogen bonding network and replacing the second amide group (Scheme 1).

In our initial approaches, we replaced  $R_2$  with highly substituted sulfonamides or tertiary amides.<sup>34</sup> However, a balance between LMP7 specificity, good metabolic stability, and sufficient permeability could not be achieved. In order to improve the physicochemical profile and lower tPSA, we moved our focus to  $R_2$  groups containing a reduced number of H donors and acceptors to fill the S2/S3 pockets. Additionally, we aimed to combine these with large  $R_1$  groups to allow for an optimized fit into the S1 pocket.

**Synthesis of LMP7 Inhibitors.** Since the commercial accessibility of protected  $\alpha$ -amino-boronates containing various R-groups is limited, we synthesized these building blocks (Scheme 2) to systematically explore the SAR of the S1 pocket of the iP. Starting from aliphatic, benzylic, or bicyclic methylene bromides 5, like 3-(bromomethyl)benzofuran, Pd-catalyzed borylation applying established protocols<sup>35</sup> led to the corresponding pinacol boronates 6 in good yields. In order to enable the stereoselective introduction of the chiral  $\alpha$ -amino

substituent, the pinacol boronates were converted into (+)-pinanediol boronates 7 as a chiral directing group using a transesterification protocol. Matteson homologation<sup>36</sup> applying (dichloromethyl)-lithium at low temperatures ( $-78$  to  $-100$  °C) and anhydrous  $ZnCl_2$  as a catalyst led to diastereoselective formation of  $\alpha$ -S-chloro boronates 8 usually with good stereoselectivity based on GC-analysis. Nucleophilic displacement of the chlorine substituent with N-lithiohexamethyldisilazane followed by cleavage of the silyl groups using HCl or trifluoroacetic acid yielded the desired R-configured derivatives 10, in most cases as solid salts, which could be stored at  $-20$  °C without degradation or epimerization.

These  $\alpha$ -aminoboronic acid building blocks were then coupled with acids using standard coupling reagents such as HATU to obtain the corresponding amides 12 in good yields (Scheme 3). At this stage, the stereochemical purity could also be readily determined by chiral supercritical fluid chromatography (SFC). In order to further improve the stereochemical purity of the desired R-diastereomers and to investigate the activity of the S-diastereomers, a chiral separation of both diastereomers was performed on a preparative scale for selected examples. However, the S-configured diastereomer proved to be significantly less active on LMP7 than the corresponding R-diastereomer. These observations confirm those previously reported by Zhu et al.<sup>32</sup> In all cases investigated, the R-configured diastereomers were between

10- and 100-fold more active on LMP7 and minor amounts of *S*-isomers did not impair the SAR evaluations. Consequently, mixtures containing low amounts of *S*-diastereomers could be readily used in biochemical experiments for determination of IC<sub>50</sub> values. In our hands, the deprotection of the (+)-pinanediol boronates 13 was most effectively achieved by a biphasic transesterification method applying isobutylboronic acid<sup>37</sup> in order to obtain the free boronic acid derivatives 14 after lyophilization as amorphous powders. Crystalline trimers comparable to those previously reported with bortezomib<sup>38</sup> could be finally obtained by recrystallization.

**SAR of R<sub>1</sub> (Tables 2 and 3).** We began our SAR exploration of the S1 pocket using compounds containing a benzyl group as R<sub>2</sub> (see Table 2), in which a bending induced by the methylene linker allowed the phenyl moiety to interact with Cys48 in the LMP7 subunit via van der Waals interactions. Despite not being the best choice in terms of potency, benzyl resulted in LMP7/ $\beta$ 5 selectivity gains superior to other R<sub>2</sub> groups with longer linkers like ethylene or propylene (data not shown). Direct attachment of phenyl to the amide resulted in a loss of potency.

The first compound of this series (Table 2, 15) harboring an isobutyl group as R<sub>1</sub> yielded only modest IC<sub>50</sub> values of 1000 and 15,000 nM against human LMP7 and  $\beta$ 5, respectively, indicating that the high activity of bortezomib or ixazomib toward LMP7 is mainly driven by the H-bond interactions of the dipeptidyl moiety in S2/S3. Changing R<sub>1</sub> to benzyl (16) led to a 6-fold improvement in potency for LMP7, whereas activity for  $\beta$ 5 remained unchanged. Further optimization of the substitution pattern of the phenyl group revealed that small nonpolar substituents like methyl or chloro in para and meta

positions further enhanced potency toward LMP7 and resulted in biochemical IC<sub>50</sub> values below 100 nM (17, 19, and 20), likely as a result of enhanced lipophilic interactions with the S1 pocket of LMP7. In terms of selectivity, the best ratios were observed for compounds containing either 3,4-dimethyl or 2,4-dimethyl substitution patterns (ratio: >150 for 18 and 19). While the larger LMP7 S1 pockets nicely accommodated these more sterically demanding moieties, they were not compatible with the more sterically restricted  $\beta$ 5 S1 pocket. This resulted in improved LMP7 selectivity for these examples. Similar trends were also observed in proteolytic cleavage assays in A549 cells (cellular  $\beta$ 5 assay, Table 1) and human peripheral blood mononuclear cells (PBMCs; cellular LMP7 assay, Table 1) applying specific luminogenic substrates.<sup>30</sup> Although cellular selectivity ratios were generally smaller compared to those observed in biochemical assays, significant selectivity was confirmed for 18 and 19. As mentioned above, inverting the configuration at the stereocenter reduced both LMP7 activity and selectivity in biochemical and cellular assays, as exemplified by compound 19 versus 21.

Docking studies with 4 employing our crystal structure suggested that bicyclic aromatic structures may overlay well with the selectivity-maximizing 3,4-dimethylphenyl moiety. Indeed, replacement of the 3,4-dimethyl phenyl in R<sub>1</sub> by 2-benzofuranyl (22, Table 3) gave comparable results to 19. Introduction of a regioisomeric 3-benzo-furanyl group further enhanced LMP7 potency by 10-fold into the single digit nM IC<sub>50</sub> range and simultaneously improved biochemical selectivity versus  $\beta$ 5 to >400-fold (23). Notably, 23 also led to a robust increase in LMP7 cellular inhibition into the low two-digit nM range. Encouraged by these results, various other

bicyclics like 2-naphthalene, 3-naphthalene, 3-benzothiophene, 3-N-methylindole, or 3-N-methylindazole (not reported here) were investigated but none of these outperformed the 3-benzofuranyl group in terms of potency and selectivity.

The favorable physicochemical profile (MW, 323 g/mol; tPSA, 83Å<sup>2</sup>; log P, 3.5; log D, 1.0; kinetic solubility, >200 μM) and high metabolic stability in mouse and human liver microsomes qualified **23** for examination of its *in vivo* PK properties. After *i.v.* application in mice, **23** showed acceptable clearance (CL), volume of distribution (V<sub>ss</sub>), and half-life

(*t*<sub>1/2</sub>) values of 0.18 L/h/kg, 2.25 L/kg, and 0.37 h, respectively. The oral bioavailability of **23** was 37% when applied at 0.5 mg/kg. Although benzofuranes are commonly considered to be metabolically labile,<sup>39</sup> in the case of **23**, the presence of the nearby polar boronic acid likely prevented oxidative metabolism, which is usually observed for these kinds of electron-rich heterobicyclics.

We next examined whether modifications by small substituents could further enhance the selectivity of compounds containing 3-benzofuranyl. While substituents such as

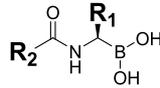

chloro were not allowed at the 2-position (exemplified by **24**), F, Cl, Me, or OMe at position 7 (**25–28**) or 6 and 7 (**29**) was tolerated but had no significant positive effect on either activity or selectivity. In another approach, we investigated the influence of partial saturation of the oxo heterobicycle and tested both stereoisomers after chiral separation. The *S*-stereoisomer (**31**) failed to fit into the LMP7 S1 pocket and was only weakly active. In contrast, *R*-stereoisomer **30** served as a potent inhibitor of LMP7 activity and showed increased selectivity against  $\beta 5$ . Replacing 7-chloro with 7-methyl led to an exquisitely selective compound (**32**) within this subseries, as demonstrated in both biochemical and cellular assays. Of note, this improvement in selectivity was only accompanied by a relatively modest reduction of cellular LMP7 potency compared to **23**.

**SAR of R<sub>2</sub> (Tables 4 and 5).** Having identified potent and selective R<sub>1</sub> residues, we next shifted our focus toward the optimization of the R<sub>2</sub> group. We maintained the synthetically tractable 3-benzo-furanyl group as R<sub>1</sub> and replaced the phenyl moiety of R<sub>2</sub> with various N-containing mono- or bicyclics (Tables 4 and 5). These retained attractive biochemical potency as exemplified by **33–37**. However, unsurprisingly, these modifications reduced biochemical and cellular selectivity toward LMP7, likely as a result of enhanced interactions by the additional H-bond acceptors with the backbone of both the  $\beta 5$  and LMP7 subunits. Intensive efforts to improve LMP7 specificity by introduction of substituents (e.g., halogen, alkoxy, amides, etc.) at the phenyl ring of R<sub>2</sub> had little effect compared to **23**. One of the few exceptions was compound **38** carrying an *ortho*-nitrile group. Combination of this R<sub>2</sub> group with (3*S*)-2,3-dihydro-1-benzofuran-3-yl (**39**) or its 7-chloro (**40**) or 7-methyl (**41**) derivatives as R<sub>1</sub> led to derivatives with impressive biochemical  $\beta 5$  splits (>1000-fold) as well as improved selectivity (>400-fold) in cells. However, despite possessing a good overall physicochemical profile (e.g., compound **39**: MW, 350 g/mol; tPSA, 103 Å<sup>2</sup>; log *P*, 1.75; log *D*, 1.3; kinetic solubility, >200 μM) and acceptable metabolic stability in mouse (37 μL/min/mg protein) and human liver microsomes (<10 μL/min/mg protein), an *in vivo* mouse PK study with **39** showed a slightly higher clearance following i.v. application (1.97 L/h/kg) than for compound **23** and a half-life of 0.71 h, while the volume of distribution (*V*<sub>ss</sub>) was 1.88 L/kg. Bioavailability was found to be 13% when applied at 0.5 mg/kg.

Moving back to the 3-benzo-furanyl group as R<sub>1</sub>, we decided to redesign R<sub>2</sub> by switching from flat aromatic groups to three-dimensional saturated moieties containing H-bond acceptors to potentially enable more specific interactions. Surprisingly, the introduction of  $\alpha$ - or  $\beta$ -ethers already led to slight improvements in both biochemical LMP7 potency and selectivity (**43** and **44**), which contrasted to alkyl moieties like the acetyl derivative **42**. Based on our crystal structure, this observation can be rationalized by formation of a new H bond between the backbone NH of Ala49 and the ether oxygen (Figure 3A).

Similar effects on potency and selectivity were observed when oxygen was incorporated into the 2- or 3-position of five- or six-membered rings as exemplified by compounds **45–48**, while the corresponding purely carbocyclic cyclo-pentyl or hexyl derivatives (data not shown) were only weakly active on LMP7. Based on the docking poses of **47** and **48**, a clear discrimination of the preferred stereochemistry was not predictable and indeed both compounds exhibited similar

IC<sub>50</sub> values in the biochemical LMP7 assay. Productive hydrogen bonding requires orientation of the tetrahydrofuran oxygen toward the peptide bond (formed by Ala49-Cys48). However, this also required the furan system to adopt an energetically unfavorable conformation. Freezing of this bioactive conformation was achieved by incorporation into a bicyclic system like the 7-oxabicyclo[2.2.1]heptane system, which is only rarely used in drug design. Indeed, this approach led to the identification of compounds **49** and **50**, which both exhibit an exo-stereochemistry in the bicyclic system. Compound **50** combined high biochemical potency and selectivity, which translated well into cellular assays. In contrast, the endo isomers **51** and **52**, which do not allow optimal positioning of the ether oxygen, were only moderately active.

The anticipated H-bond formation with the peptidic backbone in the S2 pocket could be confirmed by the generation of an additional cocrystal structure of **50** with the 20S iP, which is shown in Figure 3.<sup>40–42</sup> As a result of the

<sup>a</sup>All assay data represent the geometric mean including standard deviation of a minimum of two independent experiments in duplicates.

bicyclic system, conformational changes are highly constrained and prevent interaction between the ether oxygen and the peptidic backbone of the other iP and cP subunits.

Cyclic ethers like THF are known to be prone to CYP-mediated oxidation in the alpha-position<sup>43</sup> and are usually not regarded as desirable structural motifs in drug design. THF derivatives have been even used as prodrugs<sup>44</sup> due to their rapid oxidative cleavage. Indeed, our metabolic studies suggested an elevated oxidative metabolism, which was more pronounced for **45** and **46** and surprisingly low for **47** and **48**.

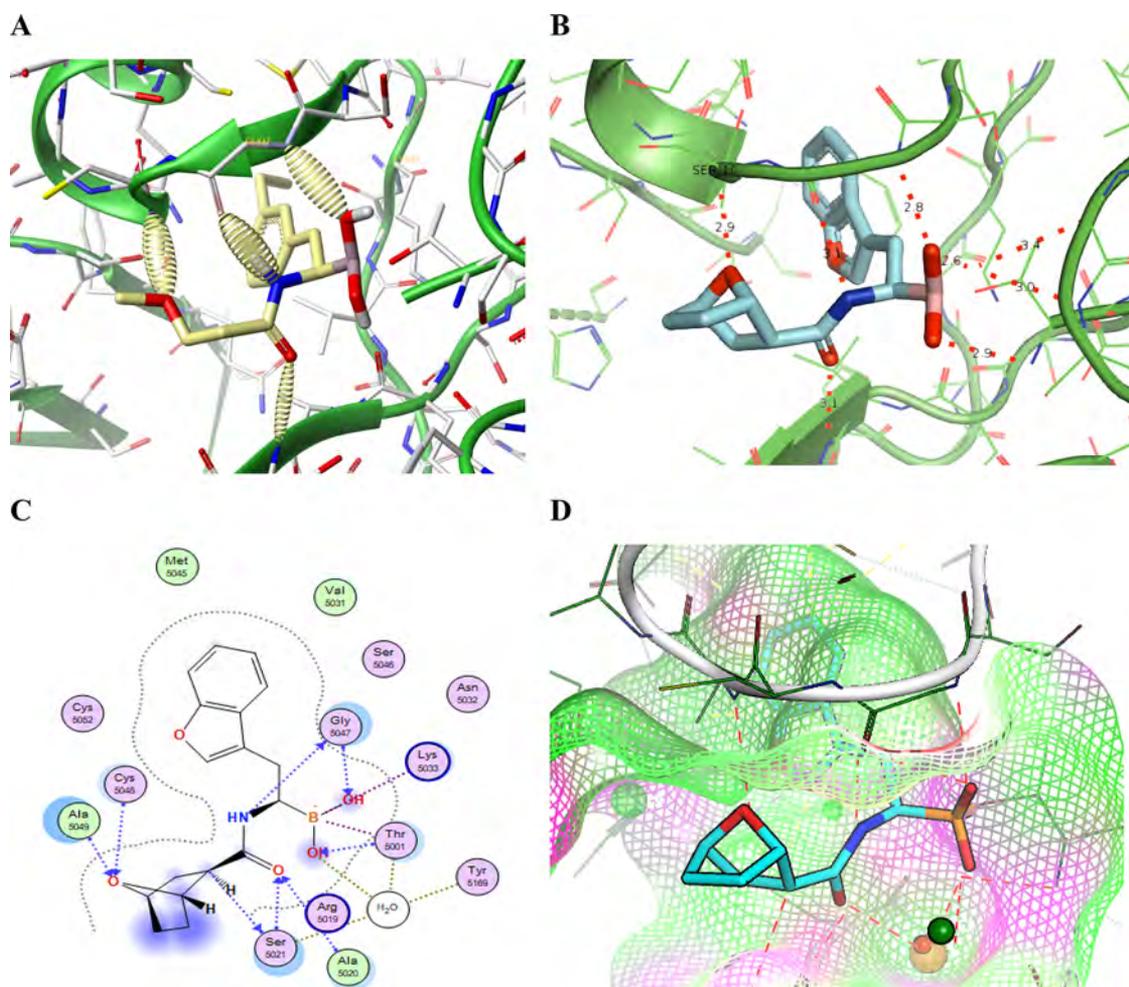

Notably, the bicyclic ether motif in compounds **49** and **50** was metabolically beneficial despite its slightly higher lipophilicity (Table 6). Improved stability of bicyclic ether amides toward metabolism has also been reported recently for CXCR7 modulators.<sup>45</sup> Additionally, the metabolic stability of compound **50** was confirmed in mouse and human hepatocyte

studies, which indicated clearance values of 15 and 6.2  $\mu$ L/min/ $10^6$  cells, respectively. The incorporation of the alpha-carbon as a bridgehead into a bicyclic system likely prevents its metabolism either due to steric reasons or because the constrained pyramidal conformation does not allow a sufficient stabilization of the radical intermediate that is usually formed during CYP-mediated metabolism.

In addition to its high biochemical ( $IC_{50}$  = 3.6 nM) and cellular ( $IC_{50}$  = 3.4 nM) potency against the LMP7 subunit, compound **50** was metabolically stable and displayed a favorable physicochemical profile (MW, 329 g/mol; tPSA, 92 Å<sup>2</sup>; log *P*, 2.3; log *D*, 1.1; kinetic solubility, >200  $\mu$ M) and acceptable permeability ( $P_{app,AB}$ :  $8.2 \times 10^{-6}$  cm/s, ER: 2.8). Biochemical assays with each iP and cP proteolytic subunit confirmed the exquisite LMP7 selectivity of **50**, exemplified by the lack of inhibition of  $\beta$ 1,  $\beta$ 2,  $\beta$ 1i, and  $\beta$ 2i up to the highest tested concentration of 30  $\mu$ M and the greatly reduced inhibition of  $\beta$ 5 ( $IC_{50}$  = 2500 nM; Table 7). Jump dilution experiments revealed a prolonged target occupancy in a range of several hours.<sup>41,42</sup> Based on these attractive features, **50** was chosen for extended *in vitro* selectivity profiling, including a selection of proteases (SI, Table S2) and other safety relevant targets (SI, Table S3). No potent off-target activity in the nanomolar range was observed, and only a few proteases and 5-HT2A were found to be inhibited at micromolar concentrations. In parallel, cell viability was assessed in HepG2 cells and rat and human hepatocytes by ATP depletion (Cell Titer Glo assay at 48 or 72 h). In contrast to bortezomib **1**, compound **50** consistently showed a weak cytotoxicity with  $IC_{50}$  values of 48  $\mu$ M in HepG2 cells, 64  $\mu$ M in rat hepatocytes, and 91  $\mu$ M in human primary hepatocytes (SI, Tables S4–S6). Consequently, the cellular split between significant target modulation and initial cytotoxicity is around 10,000-fold. The exquisite *in vitro* profile justified the in-depth *in vivo* characterization of compound **50** in PK and pharmacodynamic (PD) experiments.

**In Vivo Profiling of Compound 50.** After i.v. application in mice, **50** revealed overall favorable PK characteristics. Values for clearance, volume of distribution, and half-life were determined to be 0.19 L/h/kg (CL), 0.47 L/kg (V<sub>ss</sub>), and 1.71 h (*t*<sub>1/2</sub>), respectively. The oral bioavailability of **50** was ~35% when applied at 10 mg/kg (vehicle: 0.25% Methocel/0.25% Tween 20 in PBS). The dose-dependent *in vivo* antitumor activity and *in vivo* inhibition of tumor LMP7 by compound **50** were first evaluated in mice xenografted with the human MM cell line U266B1. When applied daily *per os* at 1 mg/kg, **50** achieved a significant and strong antitumor activity exemplified by sustained tumor regression (Figure 4A).

A lower daily oral dose of 0.3 mg/kg still resulted in significant tumor growth inhibition albeit less pronounced, while 0.1 mg/kg did not significantly affect tumor growth. Each dosing regimen was well tolerated in mice (Figure 4B). U266B1 tumor samples were taken from mice 1 and 6 h following the final application of the vehicle or **50** at 0.3 and 0.1 mg/kg for examination of LMP7 activity as a PD readout (Figure 4C). Consistent with the antitumor effects described above, the 0.3 mg/kg dose of **50** led to a significant reduction of tumor LMP7 activity at 1 and 6 h compared to the control group, while the 0.1 mg/kg group was without significant effect at any time point. The regression of U266B1 tumors under treatment with **50** at 1 mg/kg precluded PD assessments in this experiment. As such, a separate PK/PD experiment was performed using a single oral application of **50** at 1 and 0.3

**Figure 3.** Interactions of **44** and **50**. (A) Anticipated H-bond formation for **44**. H bonds are represented as cylindrical spheres. (B) Crystal structure of **50** (PDB ID: 7AWE). Compound **50** is shown in the LMP7 subunit. (C) Ligand interactions of **50** generated using the MOE program. Relevant interactions are indicated by dashed lines. (D) Graphical illustration of the surface of the LMP7 pocket. Green and magenta indicate lipophilic and polar surfaces, respectively.

**Table 6.** CLint Data and log *P* of Compounds 45–50

compound	45	46	47	48	49	50

<sup>a</sup>Assay data represent the mean of a minimum of three determinations including the standard deviation if applicable.

mg/kg to U266B1 tumor-bearing mice (Figure 5). In this experiment, the single treatment of **50** at 1 mg/kg significantly reduced LMP7 activity compared to the vehicle control group for up to 14 h, with LMP7 activity returning to baseline by 24 h. Consistent with the PD effects described above for repeated

application of **50** at 0.3 mg/kg, a single treatment at this same dose suppressed LMP7 activity at 1 and 6 h, yet it was without effects by 14 h. A higher dose of 1 mg/kg led to a dose-proportional increase in **50** exposure, which was associated with more prolonged suppression of tumor LMP7 activity.

**Figure 4.** *In vivo* efficacy study with **50** in the MM model U266B1. (A) Tumor growth inhibition upon once daily oral treatment with 0.1, 0.3, and 1 mg/kg of **50**. (B) Body weight of U266B1 tumor-bearing mice treated with **50**. (C) LMP7 activity was determined in tumor lysates by employing the LMP7-specific fluorescent (Ac-ANW)2R110 cleavage assay at 1 and 6 h after the last treatment. Inhibition of LMP7 in treated samples was calculated relative to vehicle-treated tumors. \*\*\* $P < 0.001$ .

Together, these data suggest that the elevated antitumor activity observed with the 1 mg/kg dose of **50**, compared to reduced dose levels, is likely explained by a longer duration of tumor LMP7 inhibition.

## CONCLUSIONS

The iP subunit LMP7 has been implicated in the pathogenesis of diverse disease settings including autoimmunity, inflammation, and selected malignancies. However, up until very recently, pharmacological assessment of the role of LMP7 in preclinical models of these diseases has been hampered by the unavailability of LMP7 inhibitors exhibiting high target selectivity and DMPK and physicochemical properties enabling *in vivo* application. Our LMP7 inhibitor discovery

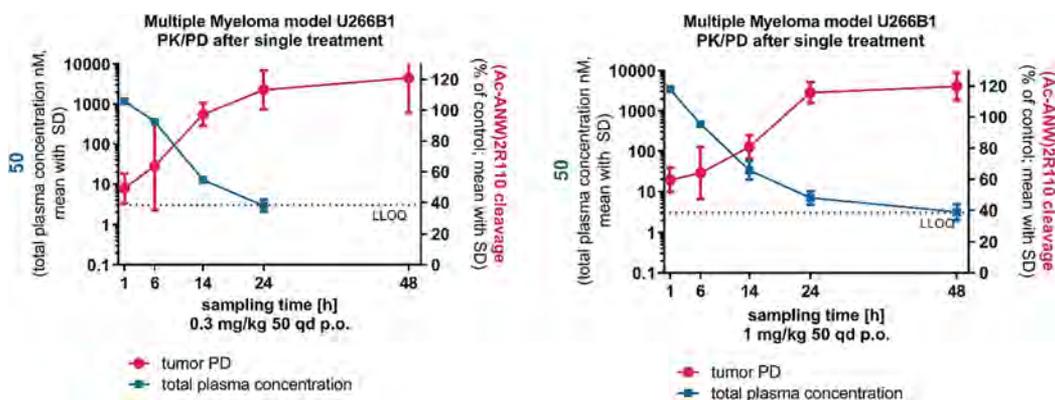

program, based on rational drug design and structural insights, culminated in the identification of the highly potent and exquisitely selective amido boronic acid-based LMP7 inhibitor **50** (M3258).<sup>41</sup> The high potency and selectivity of M3258 were achieved via the combination of the amido boronic acid scaffold with a 3-benzo-furanyl moiety as the R<sub>1</sub> group. This allowed optimal interaction with the large and lipophilic S1 pocket of LMP7 while fitting less efficiently into other iP and cP proteolytic subunits. Furthermore, the (1*S*,2*R*,4*R*)-7-oxabicyclo[2.2.1]heptane-2-carboxylic amide R<sub>2</sub> group of M3258 is positioned such that the ether-oxygen forms a highly specific H-bond interaction with the peptide backbone of LMP7 but not with other iP or cP subunits.

The attractive overall profile of M3258 enabled its application in preclinical *in vivo* models of MM. These studies provided convincing preclinical evidence that LMP7 inhibition could be an attractive pharmacological strategy in this disease. Furthermore, our findings suggest that the spectrum of iP proteolytic subunit inhibition required to achieve efficacy in preclinical MM models contrasts starkly to that in models of autoimmunity and inflammation.<sup>16–18</sup> Similar to previous reports using other selective LMP7 inhibitors,<sup>17,46</sup> we have recently reported that M3258 was not cytotoxic toward diverse primary human cell types including PBMCs.<sup>42</sup> To our knowledge, the *in vivo* activity of these other LMP7 inhibitors in MM models has not yet been reported but would be of high interest for future studies to further understand the value of LMP7 inhibition in MM. In conclusion, the findings with M3258 reported here, and those from nonclinical safety studies (Sloot et al., manuscript in preparation), supported the recent initiation of a phase I clinical trial of M3258 in relapsed/refractory MM patients (ClinicalTrials.gov identifier: NCT04075721).

## EXPERIMENTAL SECTION

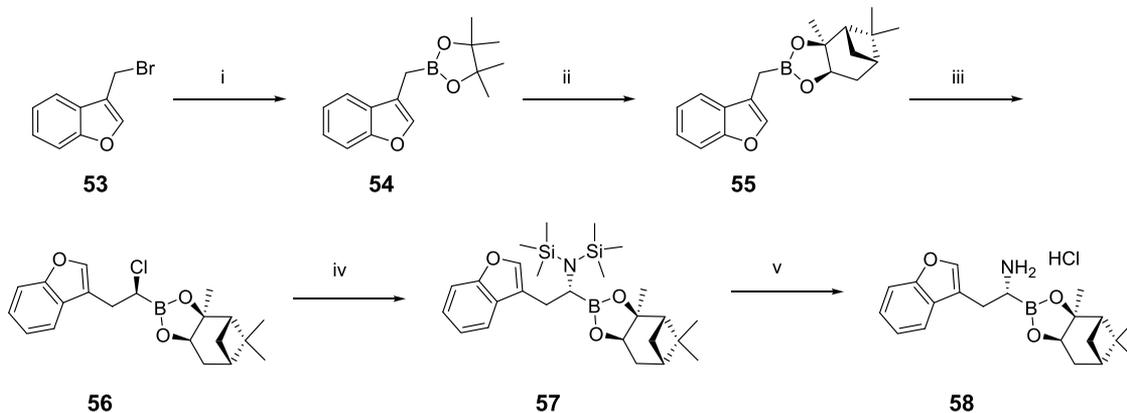

**Chemistry. General Information.** All reactions were carried out under a nitrogen atmosphere or in sealed vials unless noted otherwise. Commercial reagents and dry solvents were used as purchased without additional purification. Reactions were magnetically stirred. Nuclear magnetic resonance (NMR) spectra were recorded on Bruker NMR Spectrometers operating at 400, 500, or 700 MHz for <sup>1</sup>H and 101 or 176 Hz for <sup>13</sup>C, respectively, and are referenced to tetramethyl silane as the internal standard. Compounds reported in the publication have a purity of >95% unless noted otherwise. NMR data were processed using MestreNova software and recorded as follows: <sup>1</sup>H NMR: chemical shift ( $\delta$ , ppm), multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet), coupling constant (Hz), and integration; <sup>13</sup>C NMR: chemical shift ( $\delta$ , ppm). In the case of boronic acid samples, which usually contain varying ratios of monomer/trimer, D<sub>2</sub>O was added to sharpen the NMR peaks. High-resolution mass spectra (HRMS) were recorded on a Bruker Daltonik maXis mass spectrometer. GC–MS spectra of boronic acids have been acquired after transformation into the corresponding boronic acid ethylene glycol esters using a Waters GCT Premier (ion source temperature: 230 °C, EI ionization at 70 eV). Thin-layer chromatography (TLC) was performed on Merck Silica gel 60 F254 plates and visualized with UV light.

**LCMS Analysis.** For monitoring of reactions and purity assessment, the following devices and methods have been used: UPLC–MS method: Waters Acquity UPLC; column CORTECS C18 (1.6  $\mu$ m, 50–2.1 mm) flow: 0.9 mL/min, buffer A: H<sub>2</sub>O + 0.05% HCOOH; buffer B: MeCN + 0.04% HCOOH; T: 40 °C, 0–1.0 min 2%  $\rightarrow$  100% B; 1.0–1.3 min 100% B. HPLC method: Elite La Chrom; column: Waters XBridge C8 (3.5  $\mu$ m 50  $\times$  4.6 mm); flow: 2 mL/min; 215 nm; buffer A: 0.05% TFA/H<sub>2</sub>O; buffer B: 0.04% TFA/ACN; 0.0–0.2 min 5% buffer B; 0.2–8.1 min 5%  $\rightarrow$  100% buffer B; 8.1–

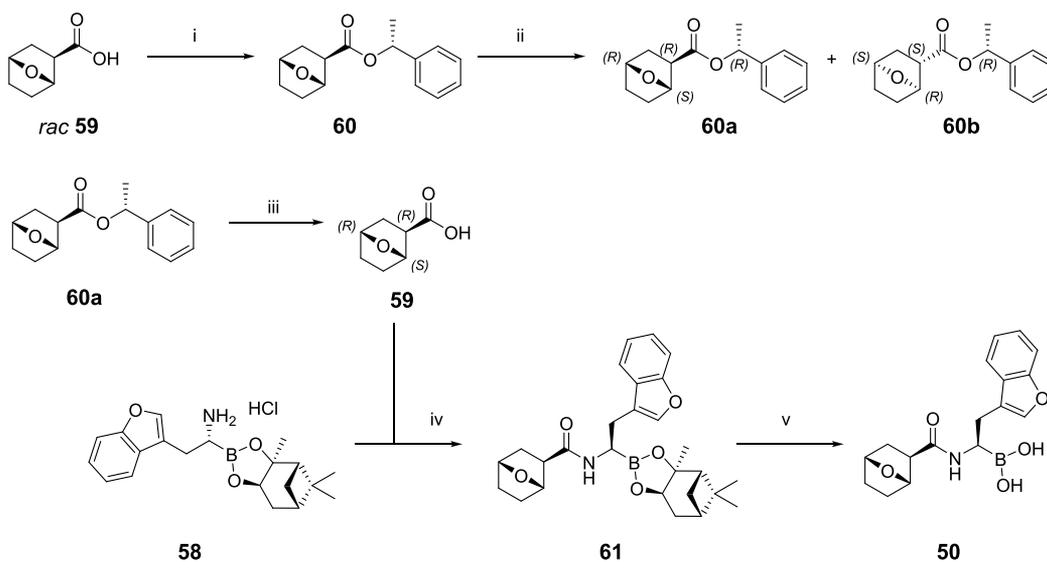

**Figure 5.** PK/PD correlation after treatment with 0.3 and 1.0 mg/kg qd p.o. **50**, respectively. Plasma samples were taken at 1, 6, 14, 24, and 48 h for PK analysis. LMP7 activity was determined in tumor lysates by employing the LMP7-specific fluorescent (Ac-ANW)2R110 cleavage assay. Inhibition of LMP7 in treated samples was calculated relative to vehicle-treated tumors. Total exposure of **50** in the plasma of mice was measured as described in the [Experimental Section](#).

<sup>a</sup>Reagents and conditions: (i) (*R*)-1-phenylethanol, DMAP, EDCI, DCM, 0 °C; (ii) chiral separation; (iii)  $H_2$ , Pd/C, THF; (iv) **59**, HATU, DMF, DIPEA, room temperature, 2 h; (v) isobutylboronic acid, 2 N HCl, MeOH, pentane, room temperature, overnight.

10.0 min 100% → 5% buffer B. Chromatography purifications were performed on a Teledyne Isco Combiflash system utilizing Redisept columns using a mobile phase composed of either ethyl acetate/heptane/ or dichloromethane/methanol.

The synthesis of **50** (M3258) is shown in Schemes 4 and 5. The synthesis of key intermediate **58** is exemplified as a typical procedure for the preparation of a protected  $\alpha$ -amino-boronate building block. Preparation of **4**–**52** followed similar methods using commercial starting materials. The descriptions of general methods, characterizations, and spectra of all final compounds are available in the Supporting Information.

**2-(Benzofuran-3-ylmethyl)-4,4,5,5-tetramethyl-1,3,2-dioxaborolane (54)**. To a solution of 3-(bromomethyl)benzofuran (7.1 g, 33.8 mmol) in degassed 1,4-dioxane (70 mL) were added bis(pinacolato)diboron (10.3 g, 40.5 mmol), potassium carbonate (13.9 g, 101.0 mmol), and tetrakis(triphenylphosphine)palladium(0) (1.9 g, 1.7 mmol), and the mixture was stirred at 85 °C for 16 h. The reaction mixture was cooled to room temperature and filtered through a celite bed. The filtrate was concentrated, and the crude was purified by flash column chromatography on silica gel, eluting with 2–5% of ethyl acetate in petroleum ether to afford the title compound (6.1 g, 69%) as yellow oil. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  7.57–7.52 (m, 2H), 7.46–7.44 (m, 1H), 7.30–7.21 (m, 2H), 2.23 (s, 2H), 1.29 (s, 12H). <sup>13</sup>C NMR (101 MHz, DMSO):  $\delta$  154.4, 141.4, 128.7, 124.0, 122.1, 119.7, 116.1, 111.1, 83.3, 24.5, 5.6 HRMS: calcd for C<sub>15</sub>H<sub>19</sub>BO<sub>3</sub> M = 258.1427; found M = 258.1426.

**2-(Benzofuran-3-ylmethyl) Boronic Acid (+)-Pinanediol Ester (55)**. To a solution of 2-(benzofuran-3-ylmethyl)-4,4,5,5-tetramethyl-1,3,2-dioxaborolane (6.1 g, 23.6 mmol) in diethyl ether (60 mL) was added (1S,2S,3R,5S)-(+)-pinanediol (6.0 g, 35.4 mmol), and the clear solution was stirred at room temperature for 12 h. The reaction mixture was washed twice with water and brine and dried over anhydrous sodium sulfate. The solvent was evaporated under vacuum, and the remaining oil was purified by flash column chromatography on silica gel, eluting with 5% of ethyl acetate in petroleum ether, to afford the title compound (6.3 g, 82%) as a solid. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  7.58–7.56 (m, 1H), 7.55–7.53 (m, 1H), 7.46–7.44 (m, 1H), 7.28–7.23 (m, 2H), 4.33 (dd,  $J$  = 1.88, 8.76 Hz, 1H), 2.34–2.32 (m, 1H), 2.28 (s, 2H), 2.22–2.21 (m, 1H), 2.08 (t,  $J$  = 5.88 Hz, 1H), 1.42 (s, 3H), 1.29 (s, 3H), 1.13 (d,  $J$  = 10.92 Hz, 1H), 0.85 (s, 3H). <sup>13</sup>C NMR (176 MHz, DMSO):  $\delta$  154.4, 141.4, 128.7, 124.0, 122.1, 119.8, 116.2, 111.1, 85.5, 77.0, 50.7, 38.9, 37.7, 35.0, 28.3, 26.8, 25.9, 23.6, 5.1. GCMS:  $m/z$ : 310. HRMS: calcd for C<sub>19</sub>H<sub>23</sub>BO<sub>3</sub>; M = 310.1740; found M = 310.1752.

**[(1S)-1-Chloro-2-(benzofuran-3-ylmethyl)] Boronic Acid (+)-Pinanediol Ester (56)**. To a cooled (–95 °C) mixture of dichloromethane (6.3 mL, 60.9 mmol) and anhydrous THF (36 mL) was added *n*-butyl lithium (1.6 M in hexanes, 14.0 mL, 22.3 mmol) over 20 min. After stirring for 20 min. at –95 °C, a solution of 2-(benzofuran-3-ylmethyl) boronic acid (+)-pinanediol ester (6.3 g, 20.3 mmol) in anhydrous THF (22 mL) was added over 20 min. Then, a solution of anhydrous zinc chloride (0.5 M in THF, 36.5 mL, 18.2 mmol) was added at –95 °C for 30 min while maintaining the inner temperature between –95 and –100 °C. The mixture was allowed to reach room temperature and stirred for 18 h, and the solvent was removed under vacuum. To the resulting oil was added diethyl ether and saturated ammonium chloride. The organic layer was dried over anhydrous sodium sulfate and concentrated *in vacuo* (residue: 7.3 g, 99%). <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  7.60–7.57 (m, 2H), 7.49–7.47 (m, 1H), 7.31–7.25 (m, 2H), 4.36–4.34 (m, 1H), 3.31–3.29 (m, 1H), 3.24–3.22 (m, 1H), 2.35–2.31 (m, 1H), 2.14–2.12 (m, 1H), 2.06 (t,  $J$  = 5.84 Hz, 1H), 1.90–1.86 (m, 2H), 1.42 (s, 3H), 1.04 (d,  $J$  = 11.04 Hz, 1H), 0.85 (s, 3H). <sup>13</sup>C NMR (176 MHz, DMSO):  $\delta$  154.4, 143.2, 127.3, 124.3, 122.4, 119.9, 116.8, 111.1, 86.1, 77.4, 50.6, 42.0, 38.6, 37.7, 34.6, 27.9, 27.8, 26.6, 25.4, 23.4. GCMS:  $m/z$ : 358.2. HRMS: calcd for C<sub>20</sub>H<sub>24</sub>BClO<sub>3</sub>; 358.1507; found: 358.1501.

**[(1R)-1-[Bis(trimethylsilyl)amino]-2-(benzofuran-3-ylmethyl)] Boronic Acid (+)-Pinanediol Ester (57)**. To a cooled (–78 °C) solution of [(1S)-1-chloro-2-(benzofuran-3-ylmethyl)]boronic acid

(+)-pinanediol ester (7.3 g, 20.3 mmol) in 40 mL of anhydrous THF was added lithium bis(trimethylsilyl)amide (1 M in THF, 25.5 mL, 25.5 mmol). The mixture was allowed to reach room temperature, stirred for 18 h, and concentrated to dryness. To the resulting residue heptane was added, and then the precipitated solid was filtered off. The filtrate was concentrated to give the crude title compound (6.7 g, 68%). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  7.60–7.59 (m, 1H), 7.50–7.45 (m, 2H), 7.28–7.24 (m, 2H), 4.31 (dd,  $J$  = 1.56, 8.70 Hz, 1H), 3.18–3.14 (m, 1H), 2.92–2.90 (m, 1H), 2.75–2.72 (m, 1H), 2.34–2.30 (m, 1H), 2.15–2.14 (m, 1H), 2.03 (t,  $J$  = 5.68 Hz, 1H), 1.88–1.80 (m, 2H), 1.39 (s, 3H), 1.30 (s, 3H), 1.01 (d,  $J$  = 10.88 Hz, 1H), 0.84 (s, 3H), 0.09 (s, 18H).

**[(1R)-1-Amino-2-(Benzofuran-3-ylmethyl)] Boronic Acid (+)-Pinanediol Ester Hydrochloride (58)**. To a stirred, cooled (–10 °C) solution of [(1R)-1-[bis(trimethylsilyl)amino]-2-(benzofuran-3-ylmethyl)]boronic acid (+)-pinanediol ester (6.7 g, 13.9 mmol) in MTBE (30 mL) under nitrogen a solution of hydrochloric acid in ethyl acetate (2.50 eq.) was added dropwise. The reaction mixture was stirred at room temperature for 3 h, resulting in a precipitate. The reaction mixture was evaporated to dryness, and the obtained solid was triturated with MTBE and filtered. The filtered solid was washed with cold MTBE and dried under vacuum to afford the title compound (3.76 g, white solid, 72%). <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  7.66 (s, 1H), 7.61–7.60 (m, 1H), 7.47–7.45 (m, 1H), 7.29–7.20 (m, 2H), 4.30–4.28 (m, 1H), 3.27–3.16 (m, 3H), 2.25–2.13 (m, 3H), 1.94 (t,  $J$  = 5.56 Hz, 1H), 1.86–1.81 (m, 2H), 1.25 (s, 6H), 1.01 (d,  $J$  = 8.00 Hz, 1H), 0.75 (s, 3H). <sup>13</sup>C NMR (126 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  154.6, 143.5, 127.3, 124.4, 122.5, 119.7, 115.1, 111.3, 86.8, 77.5, 50.5, 38.6, 37.7, 35.6, 34.4, 27.9, 26.7, 25.6, 23.5, 23.1. **(1S,2R,4R)-7-Oxa-bicyclo[2.2.1]heptane-2-carboxylic Acid (R)-1-Phenyl-ethyl Ester (60a)**. To a solution of *rac* 7-oxa-bicyclo[2.2.1]-heptane-2-carboxylic acid (4.68 g; 31.3 mmol, racemic) in dry dichloromethane (100 mL) under an atmosphere of argon (R)-1-phenyl-ethanol (4.62 mL; 37.5 mmol), 4-(dimethylamino)pyridine for synthesis (DMAP) (3.82 g; 31.3 mmol), and (3-dimethylamino-propyl)-ethyl-carbodiimide hydrochloride (EDCI) (6.73 g; 34.4 mmol) were added under stirring at 0 °C. Subsequently, the clear reaction solution was stirred overnight at room temperature. After completion of the ester formation, the reaction was quenched by adding sat. NH<sub>4</sub>Cl(aq) solution and the mixture was extracted twice with CH<sub>2</sub>Cl<sub>2</sub>. The organic layer was washed thrice with sat. NaHCO<sub>3</sub>(aq) and brine, dried over Na<sub>2</sub>SO<sub>4</sub>, filtrated, and evaporated to dryness. The crude product was purified by flash chromatography (silica gel; *n*-heptane/ethyl acetate, 0–30% ethyl acetate) to obtain 7.50 g (30.4 mmol, yield: 97.3%) of a colorless oil (HPLC: 100% pure, mixture of diastereomers). The mixture of diastereomers was separated by preparative, chiral HPLC (Chiralcel OD-H; *n*-heptane/2-propanol, 95/5; 220 nm) to obtain (1R,2S,4S)-7-oxa-bicyclo[2.2.1]-heptane-2-carboxylic acid (R)-1-phenyl-ethyl ester (3.22 g, colorless oil, yield: 41.8%, chiral HPLC 100%) and (1S,2R,4R)-7-oxa-bicyclo[2.2.1]-heptane-2-carboxylic acid (R)-1-phenyl-ethyl ester (3.14 g, oil, yield: 40.7%, chiral HPLC 100%). HRMS: calcd for C<sub>15</sub>H<sub>18</sub>O<sub>3</sub>; 246.1256; found: 246.1256.

**(1S,2R,4R)-7-Oxabicyclo[2.2.1]heptane-2-carboxylic Acid (59)**. To a solution of (1S,2R,4R)-7-oxa-bicyclo[2.2.1]-heptane-2-carboxylic acid (R)-1-phenyl-ethyl ester (46.74 g; 182.75 mmol; 1.00 equiv) in THF (233.70 mL), palladium on carbon (10% w/w) (1.94 g; 1.83 mmol; 0.01 equiv) was added. The reaction mixture is hydrogenated under a H<sub>2</sub> atmosphere at 50 °C and 5 bar pressure for 16 h. After completion of the hydrogenation, the reaction mixture was filtered through celite, and the filtrate was evaporated to dryness and taken up in pentane. The organic layer was extracted thrice with water. Subsequently, the water layer was lyophilized to obtain (1S,2R,4R)-7-oxabicyclo[2.2.1]-heptane-2-carboxylic acid (22.62 g; 159.1 mmol; yield: 87.1%) as a colorless solid. TLC: chloroform/methanol (9.5/0.5), R<sub>f</sub>: 0.5. <sup>1</sup>H NMR 400 MHz, DMSO-*d*<sub>6</sub>: 12.16 (s, 1H), 4.66 (d,  $J$  = 4.4 Hz, 1H), 4.54 (t,  $J$  = 4.4 Hz, 1H), 2.57 (d,  $J$  = 35.2 Hz, 1H), 1.91–1.86 (m, 1H), 1.65–1.37 (m, 4H), 1.34–1.33 (m, 1H). HRMS

calcd for C<sub>7</sub>H<sub>10</sub>O<sub>3</sub>: 142.0630; found: 142.0629. Optical rotation:  $[\alpha]_D^{20} = +31.9^\circ$  (ethanol, 20.16 mg/10 mL).

(1*S*,2*R*,4*R*)-7-Oxa-bicyclo[2.2.1]heptane-2-carboxylic Acid [(*R*)-2-(Benzofuran-3-yl)-1-((1*S*,2*S*,6*R*,8*S*)-2,9,9-trimethyl-3,5-dioxa-4-bora-tricyclo[6.1.1.0<sup>2,6</sup>]dec-4-yl)-ethyl]-amide (**61**). To a solution of (1*S*,2*R*,4*R*)-7-oxa-bicyclo[2.2.1]heptane-2-carboxylic acid (1.87 g; 13.18 mmol), HATU (4.62 g; 14.37 mmol), and 4-methylmorpholine (3.29 mL; 29.94 mmol) in 70 mL of dry DMF was added under ice cooling and an argon atmosphere (*R*)-2-(benzofuran-3-yl)-1-((1*S*,2*S*,6*R*,8*S*)-2,9,9-trimethyl-3,5-dioxa-4-bora-tricyclo[6.1.1.0<sup>2,6</sup>]dec-4-yl)-ethylamine hydrochloride (4.50 g; 11.98 mmol). The yellow solution was stirred for 2.5 h at room temperature. The reaction mixture was poured into 500 mL of ice-cooled, saturated NaHCO<sub>3</sub> solution and stirred for 15 min to give a precipitate, which was collected by vacuum filtration and washed with water. The obtained solid was triturated with acetonitrile, diluted with MTB-ether, and sucked off to yield (1*S*,2*R*,4*R*)-7-oxa-bicyclo[2.2.1]heptane-2-carboxylic acid [(*R*)-2-(benzofuran-3-yl)-1-((1*S*,2*S*,6*R*,8*S*)-2,9,9-trimethyl-3,5-dioxa-4-bora-tricyclo[6.1.1.0<sup>2,6</sup>]dec-4-yl)-ethyl]-amide (3.26 g, yield: 58.8%) as white solid (purity: 100%). <sup>1</sup>H NMR (700 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  9.23–9.21 (m, 1H), 7.74–7.73 (m, 1H), 7.58–7.56 (m, 1H), 7.54–7.52 (m, 1H), 7.30–7.27 (m, 1H), 7.26–7.23 (m, 1H), 4.60–4.57 (m, 2H), 4.00 (dd, *J* = 8.6, 2.3 Hz, 1H), 2.82–2.78 (m, 1H), 2.78–2.75 (m, 1H), 2.71 (dd, *J* = 9.1, 5.0 Hz, 1H), 2.66–2.62 (m, 1H), 2.17–2.12 (m, 1H), 1.91–1.86 (m, 1H), 1.84–1.80 (m, 1H), 1.77 (t, *J* = 5.6 Hz, 1H), 1.73–1.69 (m, 2H), 1.61–1.58 (m, 1H), 1.58–1.51 (m, 2H), 1.51–1.47 (m, 1H), 1.45–1.42 (m, 1H), 1.26 (d, *J* = 9.9 Hz, 1H), 1.20 (s, 3H), 1.19 (s, 3H), 0.79 (s, 3H). <sup>13</sup>C NMR (176 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  177.8, 154.5, 142.4, 128.1, 123.9, 122.2, 119.6, 118.3, 111.1, 81.8, 78.2, 75.3, 75.2, 52.0, 44.3, 41.7, 39.9, 37.5, 36.4, 34.1, 29.3, 29.2, 28.6, 27.1, 25.8, 25.1, 23.9. [(1*R*)-2-(1-Benzofuran-3-yl)-1-((1*S*,2*R*,4*R*)-7-oxabicyclo[2.2.1]heptane-2-yl)]formamido ethyl]boronic Acid (**50**). To a two-phase system of (1*S*,2*R*,4*R*)-7-oxa-bicyclo[2.2.1]heptane-2-carboxylic acid [(*R*)-2-benzofuran-3-yl-1-((1*S*,2*S*,6*R*,8*S*)-2,9,9-trimethyl-3,5-dioxa-4-bora-tricyclo[6.1.1.0<sup>2,6</sup>]dec-4-yl)-ethyl]-amide (ee = 97%, 3.45 mmol; 1.60 g) in 150 mL of *n*-pentane and 50 mL methanol were added isobutylboronic acid (13.81 mmol; 1.41 g) and 1 N hydrochloric acid (15.54 mmol; 15.54 mL) at 0 °C. The reaction was stirred at room temperature overnight. The pentane phase was discarded, and the methanolic phase was washed with pentane (3 $\times$ , 80 mL). The methanolic phase was concentrated (bath temp. below 30 °C) *in vacuo*, diluted with ice water, and alkalinized with 1 N NaOH (pH 11–12). This basic solution was extracted with DCM (3  $\times$  80 mL). The aqueous phase was acidified with 1 N HCl (pH 2) and extracted with DCM (5  $\times$  80 mL) again. The combined organic phase was dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and evaporated. The residue was dissolved in acetonitrile/water and lyophilized to give 0.697 g (yield: 61.3%) of the title compound as white powder. <sup>1</sup>H NMR (500 MHz, DMSO-*d*<sub>6</sub>/D<sub>2</sub>O):  $\delta$  7.61 (s, 1H), 7.59 (d, *J* = 7.7 Hz, 1H), 7.48 (d, *J* = 8.1 Hz, 1H), 7.29–7.25 (m, 1H), 7.24–7.19 (m, 1H), 4.48–4.45 (m, 1H), 4.42–4.40 (m, 1H), 3.12–3.08 (m, 1H), 2.84 (dd, *J* = 14.9, 5.9 Hz, 1H), 2.73 (dd, *J* = 14.9, 8.3 Hz, 1H), 2.45 (dd, *J* = 9.1, 4.9 Hz, 1H), 1.76–1.71 (m, 1H), 1.60 (dd, *J* = 11.9, 9.1 Hz, 1H), 1.52–1.44 (m, 2H), 1.43–1.34 (m, 2H). <sup>13</sup>C NMR (176 MHz, DMSO-*d*<sub>6</sub>):  $\delta$  174.6, 155.0, 142.6, 128.6, 124.7, 122.9, 120.4, 118.9, 111.7, 79.4, 75.9, 47.7, 40.7, 34.8, 29.8, 29.3, 24.9. GC–MS: calcd as ethylene glycol ester C<sub>19</sub>H<sub>22</sub>BNO<sub>5</sub>, M = 355.1591; found: 355.1568.

**Biological Assays. Biochemical Activity Testing.** Human immunoproteasomes, purified as described previously<sup>47</sup> and used at 0.25 nmol/L, or purified human constitutive proteasomes (Boston Biochem, used at 1.25 nmol/L) were preincubated for 2 h at 25 °C in 384-well plates with compounds or the vehicle dimethyl sulfoxide (DMSO) in an assay buffer containing 20 mmol/L Tris (pH 7.5), 0.03% sodium dodecyl sulfate (SDS), and 1 mmol/L ethylenediaminetetraacetic acid (EDTA). The following fluorogenic peptidic substrates (from Bachem Holding, unless stated otherwise), which undergo preferential processing by specific proteasome subunits, were added at the indicated final concentrations to assess

the inhibitory activity of compounds: Ac-nLpNLD-AMC at 50  $\mu$ mol/L for  $\beta$ 1, (Ac-PAL)2R110 (Biomol) at 80  $\mu$ mol/L for LMP2, Ac-RLR-AMC at 20  $\mu$ mol/L for  $\beta$ 2 and MECL-1, and Suc-LLVY-AMC at either 40  $\mu$ mol/L for LMP7 or at 50  $\mu$ mol/L for  $\beta$ 5.<sup>30</sup> Fluorescence was measured using an Envision 2104 plate reader (PerkinElmer) immediately following substrate addition and again after 1 h of incubation. Excitation and emission settings were used in accordance with the instructions of the provider of each peptide substrate. The inhibitory activity of compounds was ascertained by calculating the difference in fluorescence at each time point. IC<sub>50</sub> values for each compound were calculated by nonlinear regression analysis, normalized to DMSO controls, using Genedata Screener (Genedata).

**Cellular Assays.** Like in the biochemical assays, the cellular potencies of compounds were determined by measuring the proteolytic activities of proteasome subunits toward specific substrates. PBMCs (AccuCell Human PBMC) were used to assess the activity of cellular LMP7 ( $\beta$ 5i). A549 cells (ATCC no. CRL-185) were used to assess cellular  $\beta$ 5 activity. A549 cells have previously been shown to dominantly express the cP.<sup>48</sup> Both cell lines were applied at a final concentration of 3  $\times$  10<sup>5</sup> cells/ml. The assays were conducted in tissue culture plates (384 wells, white, PS) from Greiner. Compound dilution series were prepared in DMSO. The frozen cells were diluted to a stock concentration of 4.5  $\times$  10<sup>5</sup> cells/ml in DMEM/10% FCS. Cell suspension (22.5  $\mu$ L) was added in each well of the test plate. After an incubation (2 h, 5% CO<sub>2</sub>), 50 nL of compound solution or vehicle (DMSO) was added to each well. After shaking for 15 s at 900 rpm, the plates were incubated for 2 h at 7 °C (5% CO<sub>2</sub>). Then, 12.5  $\mu$ L of Proteasome-Glo detection solution was then added (prepared according to the manufacturer's instructions). For the cellular LMP7 ( $\beta$ 5i) assay, the Proteasome-Glo custom kit from Promega (Ac-ANW-luciferin substrate) was used. For the  $\beta$ 5 assay, the Proteasome-Glo Chymotrypsin-Like Cell-Based Assay kit from Promega (Suc-LLVY-luciferin substrate) was used. After shaking for 15 s at 900 rpm and 30 min of incubation at room temperature, a luminometric readout was performed. These data served as the basis for the calculation of IC<sub>50</sub> values as described above for the biochemical assays.

**Efficacy Testing In Vivo (All Animal Experiments Performed in the Manuscript were Conducted in Compliance with Institutional Guidelines).** The human MM cell line U266B1 was obtained from ATCC (TIB-196). A suspension (100  $\mu$ L) of 5 million cells in phosphate-buffered saline (PBS) mixed with 1:1 Matrigel (Becton Dickinson) was subcutaneously injected into H2d Rag2 female mice. Once tumors reached a mean tumor volume of 179 mm<sup>3</sup>, animals were assigned to treatment groups (*n* = 10) and compound **50** was administered at doses of 0.1, 0.3, and 1 mg/kg daily *per os* (formulation: 0.5% Methocel Premium K4M (Colorcon) and 0.25% Tween 20 in PBS). Mean tumor volume and standard error of the mean (SEM) were measured. Statistical analyses were performed using repeated measures analysis of covariance.

**In Vivo PD.** For PD analyses of xenograft tumors, 50–100 mg of tissue was lysed, and lysates were incubated with 10  $\mu$ M LMP7 substrate (Ac-ANW)2R110 (Biomol) for 60 min at 37 °C. Fluorescence (excitation: 485 nm, emission: 535 nm) was measured, and percent of LMP7 inhibition was calculated relative to vehicle-treated controls.

**In Vivo PK.** For plasma sampling, blood was collected from mice via an axillary cut and transferred into tubes containing sodium heparin as the anticoagulant, mixed well, and then centrifuged at 12,000g for 3 min in a refrigerated centrifuge at 4 °C. Plasma was collected and transferred into Eppendorf tubes. Samples were stabilized by the addition of 1  $\mu$ L of 22% formic acid per 10  $\mu$ L of plasma and briefly mixed. The samples were stored on ice and protected from light before freezing at –20 °C until further PK analysis by UPLC-MS/MS.

**X-ray Crystallography.** A previously described method was used for the purification of human immunoproteasomes<sup>47</sup> using the following modifications. Ion exchange chromatography on a DAE-650 M and CHT ceramic hydroxyapatite was done to isolate immunoproteasomes. Ammonium sulfate was then added to the pooled fractions to a final concentration of 1.7 mol/L. Chromatog-

raphy was then performed on Butyl-Sepharose followed by purification using a Superdex200 16/60 gel filtration column equilibrated in 50 mmol/L 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES) (pH 7.6), 100 mmol/L NaCl and 1 mmol/L dithiothreitol (DTT). For crystallization trials, fractions containing the human immunoproteasomes were concentrated to 8–10 mg/mL by ultrafiltration and stored at  $-80\text{ }^{\circ}\text{C}$ . Fractions obtained at each chromatographic step were tested for proteolytic activity using the immunoproteasome peptidic substrate cleavage assays described above, and enzymatically active fractions were pooled. Hanging-drop vapor diffusion from a 1:0.5 mixture of protein (6 mg/mL immunoproteasomes in 50 mmol/L HEPES (pH 7.6), 100 mmol/L NaCl, and 1 mmol/L DTT) and reservoir solution (0.2 mol/L sodium thiocyanate, 32–41% 2,4-methyl-pentenediol) was used to grow human immunoproteasome crystals. The quality of crystals was improved using cyclic temperature gradients between 15 and 18  $^{\circ}\text{C}$ . The immunoproteasome–cocystal complex was formed by soaking immunoproteasome apo crystals in 10 mmol/L compound 4. The immunoproteasome apo structure was solved by molecular replacement using Phaser (CCP4)<sup>49</sup> using the bovine constitutive proteasome as a starting model.<sup>50</sup> The structure of the immunoproteasome–cocystal complex was subsequently solved by molecular replacement using the structure of apo immunoproteasome. COOT<sup>51</sup> was used for model building. REFMAC5 (CCP4) and BUSTER<sup>52</sup> were used for refinement.
